on Postsecondary Outcomes

Postsecondary experiences of deaf people vary widely across the nation. National data about educational attainment and employment are available at www.nationaldeafcenter.org. This report provides current estimates of postsecondary achievement in District of Columbia. We used 5-year estimates of data from the American Community Survey (ACS), a national survey conducted by the U.S. Census Bureau, to generate the findings in this report. More information about this dataset and the analyses are shared in the *Method* section at the end of this report.

In District of Columbia,
1.2%
of 16-64 year olds are deaf

EDUCATIONAL ATTAINMENT

In the United States, deaf people attained lower levels of education than their hearing peers in 2021, according to national educational attainment data. Educational attainment also varied across gender, race, and ethnicity.

Figure 1
EDUCATIONAL ATTAINMENT

In this report, we use the term *deaf* in an all-encompassing manner to include individuals who identify as Deaf, hard of hearing, hearing impaired, late deafened, and deafdisabled.

METHOD

The data for this project are sourced from the Public Use Microdata Sample (PUMS) of 5-year estimates (2017-2021) from the American Community Survey (ACS) conducted by the U.S. Census Bureau. The PUMS offers a confidential subset of the ACS for public analysis. The ACS, a legally mandated survey, is primarily used to determine the allocation of federal funds across regions. As such, addresses of homes and group quarters, rather than individuals, are sampled, meaning that these data are meant to generalize to housing units, not individuals. Though the PUMS provides data on both individuals and housing units, only the individual-level data were utilized for this project. More information on the ACS may be found at www.census.gov/programs-surveys/acs/about.html.

The sample in these analyses comprised individuals aged 16–64. The U.S. Census gathers data on functional limitations rather than disability or identity labels so that we utilized the “hearing difficulties” variable to identify deaf individuals. The survey respondents who stated that they had “hearing difficulties” were used to represent the deaf population in these analyses. In the complete 5-year sample, there were 202,128 deaf individuals, while in District of Columbia, the deaf sample size was 329. The comparison group was those who did not report any “hearing difficulties,” labeled as hearing people. For the most part, the datasets for the group of hearing people align closely to the broader population. Thus, these analyses treat the hearing people as a benchmark—allowing for an understanding of what aspects of employment experiences might be unique, or not, to the deaf population.

The descriptive statistics in this report have been adjusted using the person-level survey weights provided by the U.S. Census. These weights aim to address the complexities of obtaining a sample representative of the U.S. population. When comparing numbers within this report, a survey-corrected t-test is employed to ascertain if differences in the numbers arose from statistical noise. These statistical tests are purely descriptive in nature and do not suggest that any of the associations described are causal in nature. Therefore, no corrections are made for any other variables when presenting these descriptive statistics.
